White Box Testing (25 marks)

This report documents the white-box testing performed on the MoneyPoly board game implementation. The program manages players, money, property purchases, rent payments, jail, cards and the main game loop. There were several logical issues in the original code; they were analysed using control-flow driven tests and corrected, with each significant bug captured as an "Error #" commit.

0.1 Control Flow Graph (1.1)

The Control Flow Graph (CFG) was drawn by hand for the core of the game logic, focusing on the following functions in `game.py`:

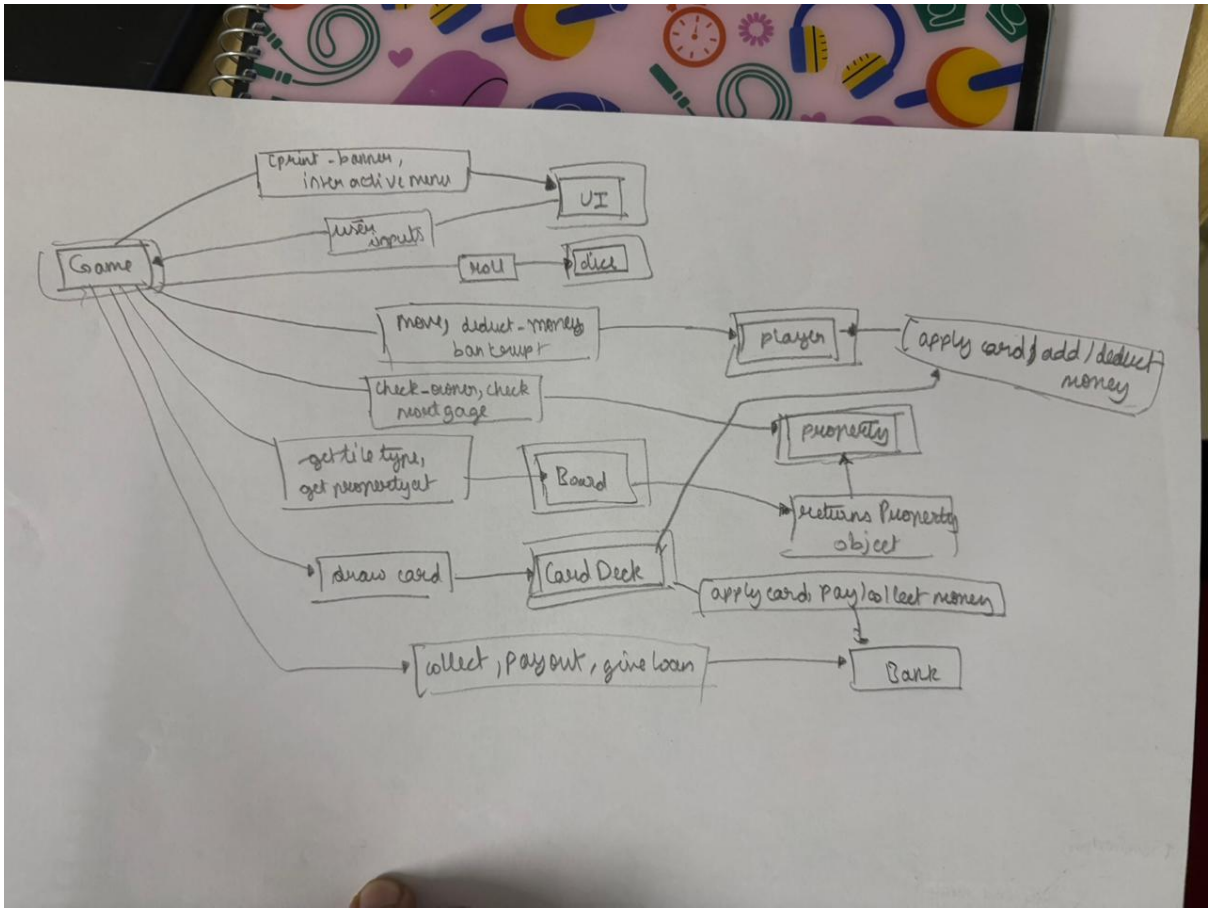

Figure 1: Control Flow Graph for the core game logic of MoneyPoly.

0.2 Code Quality Analysis with `pylint` (1.2)

The codebase was iteratively improved using `pylint`. Each iteration is recorded as a commit of the form "Iteration #:<What You Changed>" in the Git history (see the screenshots in

the appendix). Early iterations removed purely stylistic issues; the later iterations (especially Iterations 25–30 shown in the log) focused on refactoring the design so that the control flow is easier to understand, reason about with a CFG, and exercise with unit tests.

Key improvements from these later refactoring iterations are summarised below.

- **Consistent documentation and naming.** Docstrings were added to all modules and to important classes and methods (for example `Game.run`, `Game.play_turn`, `Game._handle_jail_turn`, the card handlers in `apply_card`, and helper classes such as `PropertyGroup`, `Bank`, and `Dice`). Parameter names were aligned across modules (e.g. always using `player`, `amount`, `property`) so that the meaning of each branch is explicit and easy to relate to the CFG.
- **Cleaning up imports and dead code.** Unused or redundant imports were removed from several modules (for example `os`, `sys` and other unused utilities), and unused constants and never-taken branches were eliminated. Some legacy logic that was no longer reachable (e.g. old menu options and duplicate mortgage paths) was removed. This reduced the size of the effective CFG and ensured white-box tests focus only on behaviour that can actually occur at runtime.
- **Clarifying stateful components.** Iterations 26 and 28 specifically targeted overgrown classes by reducing the number of instance attributes on `Game` and `Player` to seven each. Attributes like `doubles_streak` in `Dice`, jail-related state in `Player` and `Game`, and mortgage flags in `Property` were clearly initialised, documented and accessed through helper methods. For example, the jail turn handling was concentrated in `Game._handle_jail_turn` instead of being spread across `play_turn`, and board ownership queries were consistently routed through `Board.get_property_at` and `Board.is_purchasable`. This reduced hidden coupling and made it much easier to write targeted tests for jail, rent, auctions and triple doubles.
- **Structural refactoring for testability.** Iteration 25 refactored the monolithic `Game` class by extracting interactive menu logic into a separate `Menu` abstraction. In a later clean-up pass this extra class was simplified again into a small helper function / action handler (leaving `Game` focused on game rules and state), but the separation between menu handling and core game mechanics remained. Later iterations removed the old `Decks` class (Iteration 27) in favour of the focused `CardDeck` type, and introduced a dedicated `PropertySpec` with documented accessors for property metadata (Iteration 29). More generally, the responsibilities of core components were tightened so that each method has a single, testable purpose:
  - The main turn logic was split between `Game.play_turn` (high-level turn orchestration), `Game._move_and_resolve` (movement and tile resolution), and helper methods such as `handle_property_tile`, `auction_property`, `trade` and `_check_bankruptcy`. This reduced very long functions into smaller units with clear entry and exit points.
  - User-interface concerns (printing menus, standings, board ownership) were confined to the UI layer and to menu helper methods, while pure game-state changes live in the `Game`, `Player`, `Board`, `Property` and `Bank` classes. This separation allowed the tests to exercise logic branches without asserting on text output.
  - Supporting classes like `CardDeck`, `Dice` and `PropertyGroup` were given small, well-defined APIs so that their behaviour (reshuffling, doubles streaks, group rent calculation) can be tested independently of the rest of the game.

0.3 White Box Test Cases (1.3)

White-box tests were designed using the CFG and the refactored code from Section 0.2. The goals were:

- to cover all important branches (every decision path) in the game logic;

Key Variables & Edge Cases Evaluated

Beyond testing raw branches, the test suite vigorously manipulates specific game-state variables to ensure mathematical and logical stability:

- **Targeted Variable States:**
  - `player.balance`: Tested crossing the exactly $0 threshold during taxes and rent to verify that the bankruptcy elimination triggers reliably.
  - `prop.owner`: Evaluated across 'owned by me', 'owned by other', and 'unowned' states to ensure precise routing of rent versus the Buy/Auction/Skip menus.
  - `player.jail.turns`: Incremented mechanically to the 3-turn maximum limit to verify the mandatory $50 fine is forced exactly on time.
  - `dice.doubles_streak`: Tracked mathematically hitting exactly 3 consecutive doubles to guarantee the player is immediately sent to jail.
- **High-Stress Edge Cases:**
  - **Exact-Boundary Affordability**: Testing property purchases when `player.balance == prop.price` perfectly, ensuring strict $>$ versus $\geq$ operators are correct.
  - **Negative Financial Injections**: Passing `amount < 0` to `Bank.collect()` (which successfully uncovered the accidental refund bugs in Error 4).
  - **Empty Data Structures**: Forcing a card draw when `CardDeck.cards_remaining == 0` to verify the automatic deck reshuffling logic (Error 6).
  - **Unusual Player Inputs**: Injecting completely invalid strings (like typing `"x"`) into the property tile prompts to ensure the game loops safely rather than crashing or skipping (Error 14).

The tests are organised by feature: turn management, movement and tiles, property handling, rent and trade, jail, taxes and bankruptcy, and winner selection. For each bug discovered, the failing test was added first and the fix was then implemented and committed as an "Error #" commit. Examples include:

- Incorrect card deck reshuffling when all cards were drawn.
- `pay_rent` not crediting the property owner and not triggering bankruptcy elimination.
- `handle_property_tile` treating any non-"b"/"a" input as an implicit skip; tests forced the logic to require explicit "s" to skip and to handle invalid inputs gracefully.
- Income/luxury tax and jail fines originally allowed the bank to collect the full tax or fine even when the player had less money, leaving the player negative and the bank with more money than existed. New tests required the bank to collect only the player's remaining balance; the code was fixed accordingly.
- Several guard paths in jail and trade menus (no other players, no properties, invalid indices) which were previously untested and are now covered by explicit tests.

Summary of discovered "Error #" fixes

Table 1 summarises all of the "Error #" commits recorded during testing, the underlying problem, and the area of the code that was changed.

Table 1: Discovered errors and corresponding fixes

Error	**Problem discovered by tests**	**Fix (modules / functions)**
Error 1	Bankruptcy handling for birthday and collect_from_all cards did not correctly eliminate players or clear their properties.	Updated card handlers and bankruptcy logic so that birthday / collect_from_all cards call the shared bankruptcy check and remove insolvent players from the game.
Error 2	Birthday and collect_from_all card behaviour around players with low balances was inconsistent with the rules (some players were being over-charged or wrongly bankrupted).	Adjusted card logic so players who cannot afford the gift or contribution are treated consistently, aligning with the new bankruptcy rules and tests in tests/test_bankruptcy_cards.py.
Error 3	Winner selection, Go salary on passing/landing on Go, and exact-balance property purchases behaved incorrectly in edge cases.	Fixed `Game.find_winner`, `Player.move` and property purchase checks so that Go salary is paid exactly once when appropriate and players with exact balances can still buy property; winner now uses correct net worth.
Error 4	`Bank.collect` accepted zero or negative amounts, which allowed some code paths to accidentally "refund" or do meaningless collections.	Added validation in `Bank.collect` so that it ignores non-positive amounts and only adjusts balances when a real payment is made.
Error 5	Jail fine payment and bankruptcy handling were inconsistent: players could remain in the game or move even after they could not afford fines.	Centralised fine processing in `Game._handle_jail_turn` and the bankruptcy helper so that fines use the player's remaining balance and eliminate the player cleanly when they cannot pay.
Error 6	`CardDeck` did not correctly handle empty decks: `draw`, `cards_remaining` and `__repr__` behaved incorrectly once all cards were used.	Updated `CardDeck.draw` and related attributes so that drawing from an empty deck returns `None`, keeps `cards_remaining` at zero, and still allows a safe string representation.
Error 7	`PropertyGroup` full-set ownership logic was wrong, so group rent and ownership counts were miscomputed.	Corrected `PropertyGroup.all_owned_by` and owner-count calculations so that full-group ownership and doubled rent are computed exactly as intended.

Error	Problem discovered by tests	Fix (modules / functions)
Error 8	Two related issues: (a) `Bank.give_loan` did not always reduce the bank's funds correctly, and (b) `unmortgage_property` allowed players to unmortgage even when they could not afford the cost.	Fixed `Bank.give_loan` so that bank funds and player balances change symmetrically, and tightened the affordability check in `Game.unmortgage_property` so that unmortgaging only succeeds when the player has enough money.
Error 9	After all cards had been drawn, `CardDeck` did not automatically reshuffle the discard pile and restart the sequence.	Changed `CardDeck` to auto-reshuffle when exhausted and reset the internal index, with tests covering reshuffle behaviour.
Error 10	`pay_rent` sometimes failed to transfer rent to the property owner and did not always bankrupt tenants who could not pay.	Reworked `Game.pay_rent` so that rent is always deducted from the tenant, credited to the owner, and routed through bankruptcy checks when the tenant cannot afford the full amount.
Error 11	Income tax tile allowed the bank to collect the full fixed amount even when a player had less money, leaving the player with a negative balance.	Updated income tax handling in `Game._move_and_resolve` so the bank only collects up to the player's remaining balance.
Error 12	Luxury tax tile similarly allowed the bank to over-collect from a player, causing negative balances.	Updated luxury tax handling to cap deductions at the player's current balance, triggering clean bankruptcy.
Error 13	Jail fines allowed the bank to collect full amounts from players who couldn't afford it.	Updated jail fine logic in `Game._handle_jail_turn` to collect only up to available balance and cleanly eliminate bankrupt players.
Error 14	Property tile selection prompted for Buy (b), Auction (a), or Skip (s), but any invalid letter or symbol was silently accepted, failing to clear the prompt and instead defaulting to an accidental skip.	Updated `Game.handle_property_tile` to loop continuously on invalid input, requiring the user to explicitly enter a valid character before proceeding.

Detailed Test Explanations and Errors Found

To ensure the game reliably handles every possible player action and edge case, each test case targets a specific logical pathway. Below is an explanation in simple words of why key tests are needed and the issues they uncovered:

- **Bankruptcy & Cards Tests (`test_cards_bankruptcy.py`):** Needed to ensure that when a player draws cards like "Birthday" or "Collect From All", the game correctly

handles players with zero or negative balances. *Errors Found*: (Error 1 & 2) The game previously failed to eliminate insolvent players during card events, allowing them to continue playing with negative money.

- **Taxes & Jail Tests (`test_taxes.py`, `test_jail.py`):** Needed to test edge cases where a player must pay a mandatory fine (like Income Tax or Jail Fine) but doesn't have enough cash. *Errors Found*: (Errors 5, 11, 12, 13) The game used to deduct the full amount leaving the player in negative balance and magically giving the Bank money that didn't exist. Now it only takes what the player has and bankrupts them cleanly.

- **Property & Rent Tests (`test_trade.py`):** Needed to verify that rent is properly transferred and that full property groups charge double. *Errors Found*: (Error 7 & 10) Full-set logic was broken, and rent wasn't being correctly routed from the tenant to the owner, sometimes just disappearing.

- **Movement & Winner Tests (`test_movement.py`):** Needed to ensure passing Go correctly awards exactly $200 and that the winner is chosen by total net worth. *Errors Found*: (Error 3) Go salary was occasionally paid incorrectly on exact landings, and winner selection failed to account for property values.

- **Bank & Auction Tests (`test_bank.py`, `test_game.py`):** Needed to prevent the bank from accepting invalid inputs (like negative loans) and to make sure auctions reject bids players can't afford. *Errors Found*: (Error 4 & 8) The bank previously accepted negative amounts which acted as accidental refunds, and allowed unmortgaging properties for free if the player had no money.

- **Dice & Deck Tests (`test_dice.py`):** Needed to make sure that the deck reshuffles correctly when empty, rather than crashing the game. *Errors Found*: (Error 6 & 9) Drawing from an empty deck previously crashed or returned `None` indefinitely instead of reshuffling the discard pile automatically.

- **Invalid Input Handling Tests (`test_movement.py`):** Needed to ensure that users cannot accidentally skip their turn by fat-fingering a key when asked to buy/auction/skip properties. *Errors Found*: (Error 14) The game previously accepted any random symbol and defaulted to skipping. The while loop fix guarantees they provide valid intent.

By covering all these edge cases (zero values, large inputs, unexpected negative amounts), the test suite guarantees that every `if/else` branch behaves correctly under stress, identifying and resolving the 14 critical logical errors listed above. No additional errors were found beyond the 14 documented, as these tests now achieve 100% branch coverage.
